Erasmus+ Programme
of the European Union

Ballast waters

- Vessels fundamentally rely on ballast water for safe operation as a function of their design and construction.
- When a vessel is not fully laden with cargo, additional weight, i.e. ballast water, is required to compensate for the increased buoyancy.

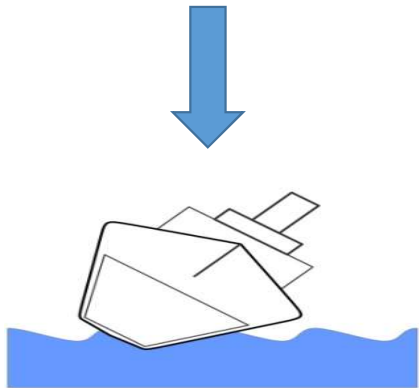

Co-funded by the
Erasmus+ Programme
of the European Union

Ballast waters

Why ballast water?

To stabilize unloaded cargo-ship.

By discharging the ballast water, organisms in the ballast water are also discharged into the new environment.

Co-funded by the
Erasmus+ Programme
of the European Union

WHAT IS IN THE BALLAST WATER DISCHARGE?

When ballast water is loaded on board the vessel, organisms present in the water are loaded as well. Many of these organisms survive ballasting operations and longer voyages, and then are discharged into the waters of another port.

Ballast water carried by vessels has been recognized as an important vector for the transfer of **Harmful Aquatic Organisms and Pathogens (HAOP)** and **Non-indigenous Species (NIS)** across natural barriers. HAOP represent one of the biggest threats to the world's oceans and seas. The transfer of HAOP via ballast water may lead to changes in the state of ecosystems and thus can have a negative impact on human health and on the economy.

Co-funded by the
Erasmus+ Programme
of the European Union

The Adriatic Sea is a unique and highly sensitive ecosystem. The economic development and social existence of the coastal states strongly depend on a clean and preserved Adriatic Sea.

The Adriatic Sea is a seaway mainly used by international shipping transporting goods to or from Europe as hinterland, with intense local shipping as well. Of serious concern is the **introduction of harmful aquatic organisms and pathogens** (HAOP) by ships' ballast water (BW). The volume of BW discharged into Adriatic Sea ports is over 10 million tons per year and due to impending projects this could soon increase considerably. The presence of HAOP in BW discharged into Adriatic ports has been proven. More than 70 NIS have been recorded in the Adriatic Sea, of which 12 are on the **"100 of the worst"** list, and most of these can be related to BW as vector. Negative HAOP impacts have already been recorded in the Adriatic Sea.

Monitoring activities in the port areas

BALLAST WATER MANAGEMENT SYSTEM FOR ADRIATIC SEA PROTECTION-BALMAS

The BALMAS project addressed on protection from Ballast Water (BW) pollution in the Adriatic area, risk prevention and protection and enhancement of the marine and coastal environment.

The BALMAS project addressed the problem of BW, which is necessary for safe navigation, but on the other hand represents a prominent vector for the transfer of Harmful Aquatic Organisms and Pathogens (HAOP) across natural barriers. The BALMAS project integrated necessary activities to enable a long-term, environmentally efficient, and financially and maritime transport sustainable implementation of Ballast Water Management (BWM) measures in the Adriatic.

Port Baseline Survey in port of Bar

PORT BASELINE SURVEY PROTOCOL

PBS are used to develop a baseline list of species including both native and non-indigenous (NIS) species present in ports, to develop a list of Harmful Aquatic Organisms and Pathogens (HAOP) and to provide a qualitative basis for monitoring the introduction of new species.

Typically, biota surveys involve sampling several different groups of organisms: hard-bottom organisms, soft-bottom benthos, plankton, and motile epifauna (eg, fish). All of these species groups should be surveyed within a comprehensive sampling protocol.

The proposed sampling protocol within the BALMAS project was applied in 12 ports of the Adriatic Sea: Bari, Ancona, Venice and Trieste in Italy, Koper in Slovenia, Pula, Rijeka, Šibenik, Split and Ploče in Croatia, Bar in Montenegro and Dures in Albania.

Port Baseline Survey in port of Bar

All positions during the four investigated seasons were classified as “excellent” according to the EU Bathing Water Directive 2006/7/EC and meet the requirements of the BWM Convention except **position P1** in June and October. Seawater quality at site P1 in June and October is considered unsatisfactory according to the requirements of the D2 - BWM convention due to the level of intestinal enterococci, although the water quality is considered sufficient according to the EU Bathing Water Directive 2006/7/EC.

 Harmful algal
 Non-indigenous species
 Ballast waters
 Adriatic Sea

An inventory of phytoplankton diversity in 12 Adriatic ports was performed with the port baseline survey. Particular emphasis was put on the detection of harmful aquatic organisms and pathogens (HAOP) because of their negative impact on ecosystem, human health, and the economy. Phytoplanktonic HAOP are identified as species, either native or non-indigenous (NIS), which can trigger harmful algal blooms (HAB). A list of 691 taxa was prepared, and among them 52 were classified as HAB and five as NIS. Records of indigenous NIS (*Pseudo-nitzschia multiseries*, *Ostreopsis* species including *O. cf. spirois*) indicate that the intrusion of non-native invasive HAOP into the Adriatic Sea has already occurred in some Adriatic ports.
